

Experiments with a Berlese Funnel

Paul J. Palmer

Trying to figure out what to call a Berlese (or Tullgren) Funnel takes more time than describing what it does. It is an apparatus for collecting microfauna from soil or leaf litter samples. The history is hard to pin down, but the earliest mention seems to be from Berlese (1905) and Tullgren (1917) so it appears that Berlese was the first to describe the apparatus, using a water bath as a heater, and then Tullgren simplified the overall arrangement by using an electric lamp as a source of heat. I'm going to stick with "Berlese Funnel" for now.

The general principle involves providing a funnel with a fine-mesh lid, an inner coarse mesh upon which the sample material is laid, and a slippery funnel leading to a receptacle with a liquid preserving agent. The use of a lamp to warm and dry the sample is an optional extra in these days of high energy costs, especially if you keep the apparatus in a warm, dry place. Mine was set up in the greenhouse with a small lamp to dry the material (See Figure ??) and a tube filled with 100% Mono Propylene Glycol (MPG) to catch the microfauna. I'm a fan of MPG as it is a good preservative, slow to evaporate, non toxic, preserves colours, and keeps specimens fairly supple. I found that most of the catch appeared after three days and little ever appeared after a week.

For my experimental trial, all the material came from locations on the nature reserve at Rutland Water: So what did I find?

My favourite and a personal first was the Pseudoscorpion *Chthonius ischnocheles* (Common Chthonid) Figure 2. It turned out that the keys to woodlice are quite easy to use so

Figure 1: Berlese Funnel set up in the greenhouse.

Figure 2: *Chthonius ischnocheles* Common Chthonid

Figure 3: *Trichoniscus pusillus* Common Pygmy Woodlouse

10.0 mm

Figure 4: *Philoscia muscorum* Common Striped Woodlouse

1.0 mm

Figure 5: Unknown *Coccinid* Scale Insect, mobile stage.
